CHAPTER – 29
ELECTRIC FIELD AND POTENTIAL
EXERCISES

1. $\varepsilon_0 = \dfrac{\text{Coulomb}^2}{\text{Newton m}^2} = I^1M^{-1}L^{-3}T^4$

   $\therefore F = \dfrac{kq_1q_2}{r^2}$

2. $q_1 = q_2 = q = 1.0$ C distance between = 2 km = 1×10^3 m

   so, force = $\dfrac{kq_1q_2}{r^2}$ $F = \dfrac{(9\times10^9)\times1\times1}{(2\times10^3)^2} = \dfrac{9\times10^9}{2^2\times10^6} = 2{,}25 \times 10^3$ N

   The weight of body = mg = 40 × 10 N = 400 N

   So, $\dfrac{\text{wt of body}}{\text{force between charges}} = \left(\dfrac{2.25\times10^3}{4\times10^2}\right)^{-1} = (5.6)^{-1} = \dfrac{1}{5.6}$

   So, force between charges = 5.6 weight of body.

3. q = 1 C, Let the distance be χ

   F = 50 × 9.8 = 490

   $F = \dfrac{Kq^2}{\chi^2} \Rightarrow 490 = \dfrac{9\times10^9\times1^2}{\chi^2}$ or $\chi^2 = \dfrac{9\times10^9}{490} = 18.36 \times 10^6$

   $\Rightarrow \chi = 4.29 \times 10^3$ m

4. charges 'q' each, AB = 1 m

   wt, of 50 kg person = 50 × g = 50 × 9.8 = 490 N

   $F_C = \dfrac{kq_1q_2}{r^2}$ $\therefore \dfrac{kq^2}{r^2} = 490$ N

   $\Rightarrow q^2 = \dfrac{490\times r^2}{9\times10^9} = \dfrac{490\times1\times1}{9\times10^9}$

   $\Rightarrow q = \sqrt{54.4\times10^{-9}} = 23.323 \times 10^{-5}$ coulomb $\approx 2.3 \times 10^{-4}$ coulomb

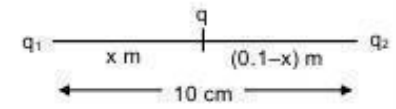

5. Charge on each proton = a= 1.6×10^{-19} coulomb

   Distance between charges = 10×10^{-15} metre = r

   Force = $\dfrac{kq^2}{r^2} = \dfrac{9\times10^9\times1.6\times1.6\times10^{-38}}{10^{-30}} = 9 \times 2.56 \times 10 = 230.4$ Newton

6. $q_1 = 2.0 \times 10^{-6}$ $q_2 = 1.0 \times 10^{-6}$ r = 10 cm = 0.1 m

   Let the charge be at a distance x from q_1

   $F_1 = \dfrac{Kq_1q}{\chi^2}$ $F_2 = \dfrac{kqq_2}{(0.1-\chi)^2}$

   $= \dfrac{9.9\times2\times10^{-6}\times10^9\times q}{\chi^2}$

   Now since the net force is zero on the charge q. $\Rightarrow f_1 = f_2$

   $\Rightarrow \dfrac{kq_1q}{\chi^2} = \dfrac{kqq_2}{(0.1-\chi)^2}$

   $\Rightarrow 2(0.1-\chi)^2 = \chi^2 \Rightarrow \sqrt{2}\,(0.1-\chi) = \chi$

   $\Rightarrow \chi = \dfrac{0.1\sqrt{2}}{1+\sqrt{2}} = 0.0586$ m = 5.86 cm ≈ 5.9 cm From larger charge

7. $q_1 = 2 \times 10^{-6}$ c $q_2 = -1 \times 10^{-6}$ c r = 10 cm = 10×10^{-2} m

   Let the third charge be a so, $F_{-AC} = -F_{-BC}$

   $\Rightarrow \dfrac{kQq_1}{r_1^2} = \dfrac{-KQq_2}{r_2^2}$ $\Rightarrow \dfrac{2\times10^{-6}}{(10+\chi)^2} = \dfrac{1\times10^{-6}}{\chi^2}$

$\Rightarrow 2\chi^2 = (10+\chi)^2 \Rightarrow \sqrt{2}\,\chi = 10+\chi \Rightarrow \chi(\sqrt{2}-1) = 10 \Rightarrow \chi = \dfrac{-10}{1.414-1} = 24.14 \text{ cm } \chi$

So, distance = 24.14 + 10 = 34.14 cm from larger charge

8. Minimum charge of a body is the charge of an electron

Wo, $q = 1.6 \times 10^{-19}$ c $\quad \chi = 1 \text{ cm} = 1 \times 10^{-2}$ cm

So, $F = \dfrac{kq_1q_2}{r^2} = \dfrac{9\times10^9\times1.6\times1.6\times10^{-19}\times10^{-19}}{10^{-2}\times10^{-2}} = 23.04 \times 10^{-38+9+2+2} = 23.04 \times 10^{-25} = 2.3 \times 10^{-24}$

9. No. of electrons of 100 g water $= \dfrac{10\times100}{18} = 55.5$ Nos $\quad$ Total charge = 55.5

No. of electrons in 18 g of $H_2O = 6.023 \times 10^{23} \times 10 = 6.023 \times 10^{24}$

No. of electrons in 100 g of $H_2O = \dfrac{6.023\times10^{24}\times100}{18} = 0.334 \times 10^{26} = 3.334 \times 10^{25}$

Total charge $= 3.34 \times 10^{25} \times 1.6 \times 10^{-19} = 5.34 \times 10^6$ c

10. Molecular weight of $H_2O = 2 \times 1 \times 16 = 16$

No. of electrons present in one molecule of $H_2O = 10$

18 gm of H_2O has 6.023×10^{23} molecule

18 gm of H_2O has $6.023 \times 10^{23} \times 10$ electrons

100 gm of H_2O has $\dfrac{6.023\times10^{24}}{18}\times100$ electrons

So number of protons $= \dfrac{6.023\times10^{26}}{18}$ protons (since atom is electrically neutral)

Charge of protons $= \dfrac{1.6\times10^{-19}\times6.023\times10^{26}}{18}$ coulomb $= \dfrac{1.6\times6.023\times10^7}{18}$ coulomb

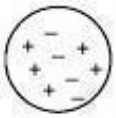

Charge of electrons = $= \dfrac{1.6\times6.023\times10^7}{18}$ coulomb

Hence Electrical force $= \dfrac{9\times10^9\left(\dfrac{1.6\times6.023\times10^7}{18}\right)\times\left(\dfrac{1.6\times6.023\times10^7}{18}\right)}{(10\times10^{-2})^2}$

$= \dfrac{8\times6.023}{18}\times1.6\times6.023\times10^{25} = 2.56 \times 10^{25}$ Newton

11. Let two protons be at a distance be 13.8 femi

$F = \dfrac{9\times10^9\times1.6\times10^{-38}}{(14.8)^2\times10^{-30}} = 1.2$ N

12. F = 0.1 N

r = 1 cm = 10^{-2} (As they rubbed with each other. So the charge on each sphere are equal)

So, $F = \dfrac{kq_1q_2}{r^2} \Rightarrow 0.1 = \dfrac{kq^2}{(10^{-2})^2} \Rightarrow q^2 = \dfrac{0.1\times10^{-4}}{9\times10^9} \Rightarrow q^2 = \dfrac{1}{9}\times10^{-14} \Rightarrow q = \dfrac{1}{3}\times10^{-7}$

1.6×10^{-19} c $\quad$ Carries by 1 electron $\quad$ 1 c carried by $\dfrac{1}{1.6\times10^{-19}}$

0.33×10^{-7} c carries by $\dfrac{1}{1.6\times10^{-19}}\times0.33\times10^{-7} = 0.208 \times 10^{12} = 2.08 \times 10^{11}$

13. $F = \dfrac{kq_1q_2}{r^2} = \dfrac{9\times10^9\times1.6\times1.6\times10^{-19}\times10^{-19}}{(2.75\times10^{-10})^2} = \dfrac{23.04\times10^{-29}}{7.56\times10^{-20}} = 3.04 \times 10^{-9}$

14. Given: mass of proton $= 1.67 \times 10^{-27}$ kg $= M_p$

$k = 9 \times 10^9$ $\quad$ Charge of proton $= 1.6 \times 10^{-19}$ c $= C_p$

$G = 6.67 \times 10^{-11}$ $\quad$ Let the separation be 'r'

$Fe = \dfrac{k(C_p)^2}{r^2}$, $\quad fg = \dfrac{G(M_p)^2}{r^2}$

Now, $Fe : Fg = \dfrac{K(C_p)^2}{r^2}\times\dfrac{r^2}{G(M_p)^2} = \dfrac{9\times10^9\times(1.6\times10^{-19})^2}{6.67\times10^{-11}\times(1.67\times10^{-27})^2} = 9 \times 2.56 \times 10^{38} \approx 1.24 \times 10^{38}$

15. Expression of electrical force $F = C \times e^{\frac{-kr}{r^2}}$

Since e^{-kr} is a pure number. So, dimensional formulae of $F = \frac{\text{dimensional formulae of C}}{\text{dimensional formulae of } r^2}$

Or, $[MLT^{-2}][L^2]$ = dimensional formulae of C = $[ML^3T^{-2}]$

Unit of C = unit of force × unit of r^2 = Newton × m^2 = Newton–m^2

Since –kr is a number hence dimensional formulae of

$k = \frac{1}{\text{dimentional formulae of r}} = [L^{-1}]$ Unit of $k = m^{-1}$

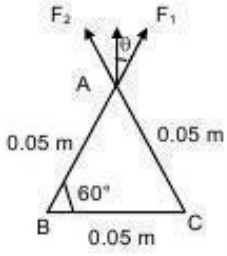

16. Three charges are held at three corners of a equilateral trangle.

Let the charges be A, B and C. It is of length 5 cm or 0.05 m

Force exerted by B on A = F_1 force exerted by C on A = F_2

So, force exerted on A = resultant $F_1 = F_2$

$\Rightarrow F = \frac{kq_2}{r^2} = \frac{9\times10^9\times2\times2\times2\times10^{-12}}{5\times5\times10^{-4}} = \frac{36}{25}\times10 = 14.4$

Now, force on A = 2 × F cos 30° since it is equilateral Δ.

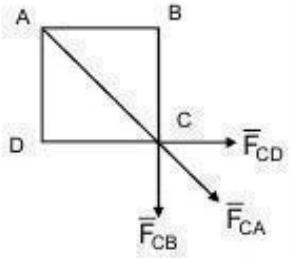

$\Rightarrow$ Force on A = $2 \times 1.44 \times \sqrt{\frac{3}{2}} = 24.94$ N.

17. $q_1 = q_2 = q_3 = q_4 = 2 \times 10^{-6}$ C

$v = 5$ cm $= 5 \times 10^{-2}$ m

so force on $\bar{c} = \bar{F}_{CA} + \bar{F}_{CB} + \bar{F}_{CD}$

so Force along × Component = $\bar{F}_{CD} + \bar{F}_{CA}\cos 45° + 0$

$= \frac{k(2\times10^{-6})^2}{(5\times10^{-2})^2} + \frac{k(2\times10^{-6})^2}{(5\times10^{-2})^2}\frac{1}{2\sqrt{2}} = kq^2\left(\frac{1}{25\times10^{-4}} + \frac{1}{50\sqrt{2}\times10^{-4}}\right)$

$= \frac{9\times10^9\times4\times10^{-12}}{24\times10^{-4}}\left(1+\frac{1}{2\sqrt{2}}\right)$ = 1.44 (1.35) = 19.49 Force along % component = 19.49

So, Resultant $R = \sqrt{Fx^2 + Fy^2} = 19.49\sqrt{2} = 27.56$

18. $R = 0.53\ A° = 0.53 \times 10^{-10}$ m

$F = \frac{Kq_1q_2}{r^2} = \frac{9\times10^9\times1.6\times1.6\times10^{-38}}{0.53\times0.53\times10^{-10}\times10^{-10}} = 82.02 \times 10^{-9}$ N

19. Fe from previous problem No. 18 = 8.2×10^{-8} N Ve = ?

Now, $M_e = 9.12 \times 10^{-31}$ kg $r = 0.53 \times 10^{-10}$ m

Now, $Fe = \frac{M_e v^2}{r} \Rightarrow v^2 = \frac{Fe\times r}{m_e} = \frac{8.2\times10^{-8}\times0.53\times10^{-10}}{9.1\times10^{-31}} = 0.4775 \times 10^{13} = 4.775 \times 10^{12}\ m^2/s^2$

$\Rightarrow v = 2.18 \times 10^6$ m/s

---

20. Electric force feeled by 1 c due to 1×10^{-8} c.

$F_1 = \frac{k\times1\times10^{-8}\times1}{(10\times10^{-2})^2} = k \times 10^{-6}$ N. electric force feeled by 1 c due to 8×10^{-8} c.

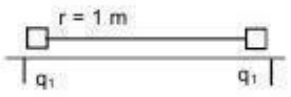

$F_2 = \frac{k\times8\times10^{-8}\times1}{(23\times10^{-2})^2} = \frac{k\times8\times\times10^{-8}\times10^2}{9} = \frac{28k\times10^{-6}}{4} = 2k \times 10^{-6}$ N.

Similarly $F_3 = \frac{k\times27\times10^{-8}\times1}{(30\times10^{-2})^2} = 3k \times 10^{-6}$ N

So, $F = F_1 + F_2 + F_3 + \ldots\ldots + F_{10} = k \times 10^{-6}(1 + 2 + 3 + \ldots\ldots + 10)$ N

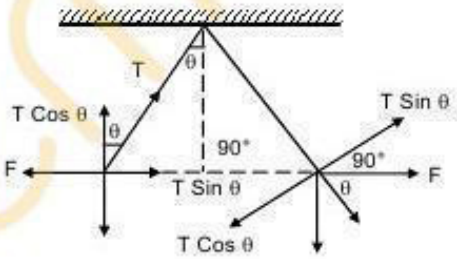

$= k \times 10^{-6} \times \frac{10\times11}{2} = 55k \times 10^{-6} = 55 \times 9 \times 10^9 \times 10^{-6} = 4.95 \times 10^3$ N

21. Force exerted = $\frac{kq_1^2}{r^2}$

$= \frac{9\times10^{9}\times2\times2\times10^{-14}}{1^2} = 3.6\times10^{-6}$ is the force exerted on the string

22. $q_1 = q_2 = 2\times10^{-7}$ c m = 100 g
l = 50 cm = 5×10^{-2} m d = 5×10^{-2} m

(a) Now Electric force

$F = K\frac{q^2}{r^2} = \frac{9\times10^{9}\times4\times10^{-14}}{25\times10^{-4}}$ N = 14.4×10^{-2} N = 0.144 N

(b) The components of Resultant force along it is zero, because mg balances T cos θ and so also.

F = mg = T sin θ

(c) Tension on the string

T sin θ = F T cos θ = mg

$\text{Tan}\,\theta = \frac{F}{mg} = \frac{0.144}{100\times10^{-3}\times9.8} = 0.14693$

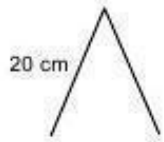

But T cos θ = $10^2\times10^{-3}\times10 = 1$ N

$\Rightarrow T = \frac{1}{\cos\theta} = \sec\theta$

$\Rightarrow T = \frac{F}{\sin\theta}$,

Sin θ = 0.145369 ; Cos θ = 0.989378;

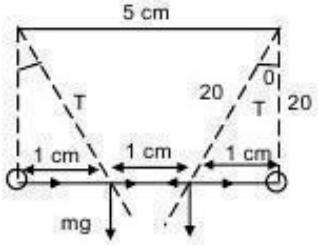

23. q = 2.0×10^{-8} c n= ? T = ? $\text{Sin}\,\theta = \frac{1}{20}$

Force between the charges

$F = \frac{Kq_1q_2}{r^2} = \frac{9\times10^{9}\times2\times10^{-8}\times2\times10^{-8}}{(3\times10^{-2})^2} = 4\times10^{-3}$ N

$mg\sin\theta = F \Rightarrow m = \frac{F}{g\sin\theta} = \frac{4\times10^{-3}}{10\times(1/20)} = 8\times10^{-3} = 8$ gm

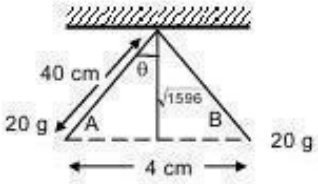

$\text{Cos}\,\theta = \sqrt{1-\text{Sin}^2\theta} = \sqrt{1-\frac{1}{400}} = \sqrt{\frac{400-1}{400}} = 0.99 \approx 1$

So, T = mg cos θ

Or T = 8×10^{-3} $10\times0.99 = 8\times10^{-2}$ M

---

24. T Cos θ = mg ...(1)
T Sin θ = Fe ...(2)

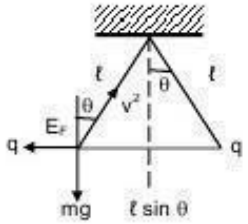

Solving, (2)/(1) we get, $\tan\theta = \frac{Fe}{mg} = \frac{kq^2}{r}\times\frac{1}{mg}$

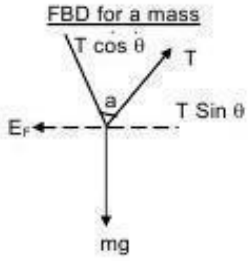

$\Rightarrow \frac{2}{\sqrt{1596}} = \frac{9\times10^{9}\times q^2}{(0.04)^2\times0.02\times9.8}$

$\Rightarrow q^2 = \frac{(0.04)^2\times0.02\times9.8\times2}{9\times10^{9}\times\sqrt{1596}} = \frac{6.27\times10^{-4}}{9\times10^{9}\times39.95} = 17\times10^{-16}c^2$

$\Rightarrow q = \sqrt{17\times10^{-16}} = 4.123\times10^{-8}$ c

25. Electric force = $\frac{kq^2}{(\ell\sin Q+\ell\sin Q)^2} = \frac{kq^2}{4\ell^2\sin^2}$

So, T Cos θ = ms (For equilibrium) T sin θ = Ef

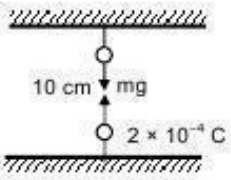

Or $\tan\theta = \frac{Ef}{mg}$

$\Rightarrow mg = Ef\cot\theta = \frac{kq^2}{4\ell^2\sin^2\theta}\cot\theta = \frac{q^2\cot\theta}{\ell^2\sin^2\theta 16\pi E_0}$

or m = $\frac{q^2\cot\theta}{\quad}$ unit.

$16\pi E_0 \ell^2 \sin^2\theta g$

26. Mass of the bob = 100 g = 0.1 kg

So Tension in the string = 0.1 × 9.8 = 0.98 N.

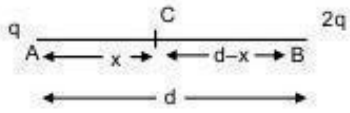

For the Tension to be 0, the charge below should repel the first bob.

$\Rightarrow F = \frac{kq_1q_2}{r^2}$ $\quad T - mg + F = 0 \Rightarrow T = mg - f \quad T = mg$

$\Rightarrow 0.98 = \frac{9\times10^9 \times 2\times10^{-4} \times q_2}{(0.01)^2} \Rightarrow q_2 = \frac{0.98\times1\times10^{-2}}{9\times2\times10^5} = 0.054 \times 10^{-9}$ N

27. Let the charge on C = q

So, net force on c is equal to zero

So $F_{\overline{AC}} + F_{\overline{BA}} = 0$, But $F_{AC} = F_{BC} \Rightarrow \frac{kqQ}{x^2} = \frac{k2qQ}{(d-x)^2}$

$\Rightarrow 2x^2 = (d-x)^2 \Rightarrow \sqrt{2}\,x = d - x$

$\Rightarrow x = \frac{d}{\sqrt{2}+1} = \frac{d}{(\sqrt{2}+1)} \times \frac{(\sqrt{2}-1)}{(\sqrt{2}-1)} = d(\sqrt{2}-1)$

For the charge on rest, $F_{AC} + F_{AB} = 0$

$(2.414)^2 \frac{kqQ}{d^2} + \frac{kq(2q)}{d^2} = 0 \Rightarrow \frac{kq}{d^2}[(2.414)^2 Q + 2q] = 0$

$\Rightarrow 2q = -(2.414)^2 Q$

$\Rightarrow Q = \frac{2}{-(\sqrt{2}+1)^2} q = -\left(\frac{2}{3+2\sqrt{2}}\right) q = -(0.343)\, q = -(6 - 4\sqrt{2})$

28. K = 100 N/m $\quad \ell = 10$ cm $= 10^{-1}$ m $\quad q = 2.0 \times 10^{-8}$ c Find ℓ = ?

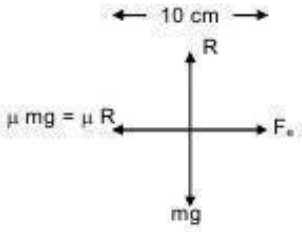

Force between them $F = \frac{kq_1q_2}{r^2} = \frac{9\times10^9 2\times10^{-8}\times2\times10^{-8}}{10^{-2}} = 36 \times 10^{-5}$ N

So, $F = -kx$ or $x = \frac{F}{-K} = \frac{36\times10^{-5}}{100} = 36 \times 10^{-7}$ cm $= 3.6 \times 10^{-6}$ m

29. $q_A = 2 \times 10^{-6}$ C $\quad M_b = 80$ g $\quad \mu = 0.2$

Since B is at equilibrium, So, Fe = μR

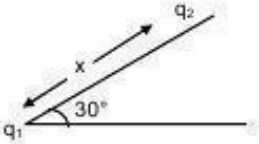

$\Rightarrow \frac{Kq_Aq_B}{r^2} = \mu R = \mu m \times g$

$\Rightarrow \frac{9\times10^9 \times 2\times10^{-6} \times q_B}{0.01} = 0.2 \times 0.08 \times 9.8$

$\Rightarrow q_B = \frac{0.2\times0.08\times9.8\times0.01}{9\times10^9\times2\times10^{-6}} = 8.7 \times 10^{-8}$ C $\quad$ Range = $\pm 8.7 \times 10^{-8}$ C

30. $q_1 = 2 \times 10^{-6}$ c $\quad$ Let the distance be r unit

$\therefore F_{repulsion} = \frac{kq_1q_2}{r^2}$

For equilibrium $\frac{kq_1q_2}{r^2} = mg \sin\theta$

$\Rightarrow \frac{9\times10^9 \times 4\times10^{-12}}{r^2} = m \times 9.8 \times \frac{1}{2}$

$\Rightarrow r^2 = \frac{18\times4\times10^{-3}}{m\times9.8} = \frac{72\times10^{-3}}{9.8\times10^{-1}} = 7.34 \times 10^{-2}$ metre

$\Rightarrow r = 2.70924 \times 10^{-1}$ metre from the bottom.

31. Force on the charge particle 'q' at 'c' is only the x component of 2 forces

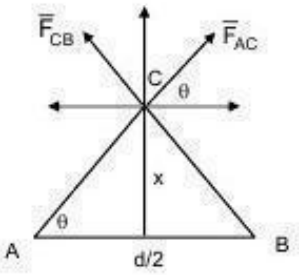

So, $F_{on\ c} = F_{CB} \sin\theta + F_{AC} \sin\theta$ $\quad$ But $|\overline{F}_{CB}| = |\overline{F}_{AC}|$

$= 2 F_{CB} \sin\theta = 2\frac{KQq}{x^2 + (d/2)^2} \times \frac{x}{\left[x^2 + d^2/4\right]^{1/2}} = \frac{2k\theta qx}{(x^2 + d^2/4)^{3/2}} = \frac{16kQq}{(4x^2 + d^2)^{3/2}} x$

dF

For maximum force $\frac{dF}{dx} = 0$

$$\frac{d}{dx}\left(\frac{16kQqx}{(4x^2+d^2)^{3/2}}\right) = 0 \Rightarrow K\left[\frac{(4x^2+d^2) - x\left[3/2\left[4x^2+d^2\right]^{1/2}8x\right]}{[4x^2+d^2]^3}\right] = 0$$

$$\Rightarrow \frac{K(4x^2+d^2)^{1/2}\left[(4x^2+d^2)^3 - 12x^2\right]}{(4x^2+d^2)^3} = 0 \Rightarrow (4x^2+d^2)^3 = 12x^2$$

$\Rightarrow 16x^4 + d^4 + 8x^2d^2 = 12x^2 \qquad d^4 + 8x^2d^2 = 0$

$\Rightarrow d^2 = 0 \qquad d^2 + 8x^2 = 0 \qquad \Rightarrow d^2 = 8x^2 \Rightarrow d = \frac{d}{2\sqrt{2}}$

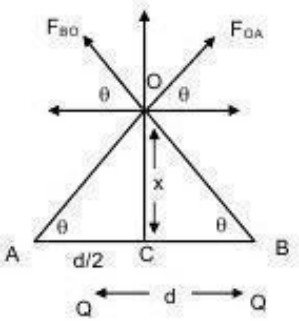

32. (a) Let Q = charge on A & B Separated by distance d

q = charge on c displaced ⊥ to –AB

So, force on 0 = $\bar{F}_{AB} + \bar{F}_{BO}$

But $F_{AO}\cos\theta = F_{BO}\cos\theta$

So, force on '0' in due to vertical component.

$\bar{F} = F_{AO}\sin\theta + F_{BO}\sin\theta \qquad |F_{AO}| = |F_{BO}|$

$$= 2\frac{KQq}{(d/2^2+x^2)}\sin\theta \qquad F = \frac{2KQq}{(d/2)^2+x^2}\sin\theta$$

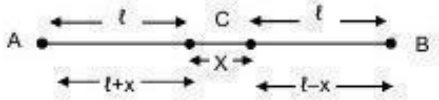

$$= \frac{4\times2\times kQq}{(d^2+4x^2)} \times \frac{x}{[(d/2)^2+x^2]^{1/2}} = \frac{2kQq}{[(d/2)^2+x^2]^{3/2}}x = \text{Electric force} \Rightarrow F \propto x$$

(b) When x << d $\quad F = \frac{2kQq}{[(d/2)^2+x^2]^{3/2}}x \quad x<<d$

$$\Rightarrow F = \frac{2kQq}{(d^2/4)^{3/2}}x \Rightarrow F \propto x \qquad a = \frac{F}{m} = \frac{1}{m}\left[\frac{2kQqx}{[(d^2/4)+\ell^2}\right]$$

So time period $T = 2\pi\sqrt{\frac{\ell}{g}} = 2\pi\sqrt{\frac{\ell}{a}}$

33. $F_{AC} = \frac{KQq}{(\ell+x)^2} \qquad F_{CA} = \frac{KQq}{(\ell-x)^2}$

Net force $= KQq\left[\frac{1}{(\ell-x)^2} - \frac{1}{(\ell+x)^2}\right]$

$$= KQq\left[\frac{(\ell+x)^2-(\ell-x)^2}{(\ell+x)^2(\ell-x)^2}\right] = KQq\left[\frac{4\ell x}{(\ell^2-x^2)^2}\right]$$

x<<< l = d/2 neglecting x w.r.t. ℓ We get

net $F = \frac{KQq4\ell x}{\ell^4} = \frac{KQq4x}{\ell^3}$ acceleration $= \frac{4KQqx}{m\ell^3}$

Time period $= 2\pi\sqrt{\frac{\text{displacement}}{\text{acceleration}}} = 2\pi\sqrt{\frac{xm\ell^3}{4KQqx}} = 2\pi\sqrt{\frac{m\ell^3}{4KQq}}$

$$= \sqrt{\frac{4\pi^2m\ell^3 4\pi\varepsilon_0}{4Qq}} = \sqrt{\frac{4\pi^3m\ell^3\varepsilon_0}{Qq}} = \sqrt{4\pi^3md^3\varepsilon_0 8Qq} = \left[\frac{\pi^3md^3\varepsilon_0}{2Qq}\right]^{1/2}$$

34. $F_e = 1.5\times10^{-3}$ N, $\quad q = 1\times10^{-6}$ C, $\quad F_e = q\times E$

$$\Rightarrow E = \frac{F_e}{q} = \frac{1.5\times10^{-3}}{1\times10^{-6}} = 1.5\times10^3 \text{ N/C}$$

35. $q_2 = 2\times10^{-6}$ C, $\quad q_1{}^2 = -4\times10^{-6}$ C, $\quad r = 20$ cm $= 0.2$ m

(E_1 = electric field due to q_1, $\quad E_2$ = electric field due to q_2)

$$\Rightarrow \frac{(r-x)^2}{x^2} = \frac{-q_2}{q_1} \Rightarrow \frac{(r-1)^2}{x} = \frac{-q_2}{q_1} = \frac{4\times10^{-6}}{2\times10^{-6}} = \frac{1}{2}$$

$$\Rightarrow \left(\frac{r}{x}-1\right) = \frac{1}{\sqrt{2}} = \frac{1}{1.414} \Rightarrow \frac{r}{x} = 1.414 + 1 = 2.414$$

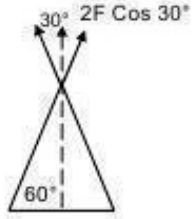

$$\Rightarrow x = \frac{r}{2.414} = \frac{20}{2.414} = 8.285 \text{ cm}$$

36. $EF = \dfrac{KQ}{r^2}$

$$5 \text{ N/C} = \frac{9\times10^9 \times Q}{4^2}$$

$$\Rightarrow \frac{4\times20\times10^{-2}}{9\times10^9} = Q \Rightarrow Q = 8.88 \times 10^{-11}$$

37. $m = 10, \quad mg = 10 \times 10^{-3}\ g \times 10^{-3}\ kg, \quad q = 1.5 \times 10^{-6}\ C$

But $qE = mg \Rightarrow (1.5 \times 10^{-6})\ E = 10 \times 10^{-8} \times 10$

$$\Rightarrow E = \frac{10\times10^{-4}\times10}{1.5\times10^{-6}} = \frac{100}{1.5} = 66.6 \text{ N/C}$$

$$= \frac{100\times10^3}{1.5} = \frac{10^{5+1}}{15} = 6.6 \times 10^3$$

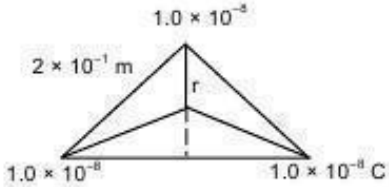

38. $q = 1.0 \times 10^{-8}\ C, \quad \ell = 20 \text{ cm}$

$E = ? \qquad V = ?$

Since it forms an equipotential surface.

So the electric field at the centre is <u>Zero</u>.

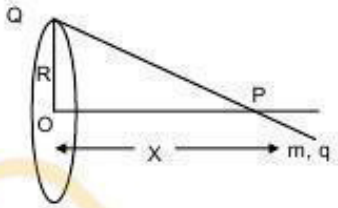

$$r = \frac{2}{3}\sqrt{(2\times10^{-1})^2 - (10^{-1})^2} = \frac{2}{3}\sqrt{4\times10^{-2} - 10^{-2}}$$

$$= \frac{2}{3}\sqrt{10^{-2}(4-1)} = \frac{2}{3}\times10^{-2}\times1.732 = 1.15\times10^{-1}$$

$$V = \frac{3\times9\times10^9 1\times10^{-8}}{1\times10^{-1}} = 23\times10^2 = 2.3\times10^3 \text{ V}$$

39. We know : Electric field 'E' at 'P' due to the charged ring

$$= \frac{KQx}{(R^2+x^2)^{3/2}} = \frac{KQx}{R^3}$$

Force experienced 'F' = $Q \times E = \dfrac{q\times K\times Qx}{R^3}$

Now, amplitude = x

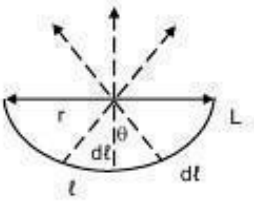

So, $T = 2\pi\sqrt{\dfrac{x}{KQqx/mR^3}} = 2\pi\sqrt{\dfrac{mR^3x}{KQqx}} = 2\pi\sqrt{\dfrac{4\pi\varepsilon_0 mR^3}{Qq}} = \sqrt{\dfrac{4\pi^2\times4\pi\varepsilon_0 mR^3}{qQ}}$

$$\Rightarrow T = \left[\frac{16\pi^3\varepsilon_0 mR^3}{qQ}\right]^{1/2}$$

40. λ = Charge per unit length = $\dfrac{Q}{L}$

dq_1 for a length dl = $\lambda \times dl$

Electric field at the centre due to charge = $k\times\dfrac{dq}{r^2}$

The horizontal Components of the Electric field balances each other. Only the vertical components remain.

∴ Net Electric field along vertical

$$d_E = 2\ E\cos\theta = \frac{Kdq\times\cos\theta}{r^2} = \frac{2kCos\theta}{r^2}\times\lambda\times dl \qquad [\text{but } d\theta = \frac{d\ell}{r} = d\ell = rd\theta]$$

$$\Rightarrow \frac{2k\lambda}{r^2}Cos\theta\times rd\theta = \frac{2k\lambda}{r}Cos\theta\times d\theta$$

$$\text{or } E = \int^{\pi/2}\frac{2k\lambda}{\quad}Cos\theta\times d\theta = \int^{\pi/2}\frac{2k\lambda}{\quad}Sin\theta = \frac{2k\lambda l}{\quad} = \frac{2K\theta}{\quad}$$

$\int_0 r$ $\int_0 r$ r Lr

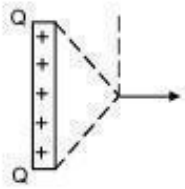

but $L = \pi R \Rightarrow r = \dfrac{L}{\pi}$

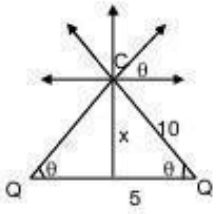

So $E = \dfrac{2k\theta}{L\times(L/\pi)} = \dfrac{2k\pi\theta}{L^2} = \dfrac{2}{4\pi\varepsilon_0}\times\dfrac{\pi\theta}{L^2} = \dfrac{\theta}{2\varepsilon_0 L^2}$

41. $G = 50\ \mu C = 50 \times 10^{-6}\ C$

We have, $E = \dfrac{2KQ}{r}$ for a charged cylinder.

$\Rightarrow E = \dfrac{2\times9\times10^9\times50\times10^{-6}}{5\sqrt{3}} = \dfrac{9\times10^{-5}}{5\sqrt{3}} = 1.03\times10^{-5}$

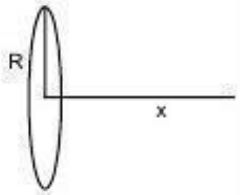

42. Electric field at any point on the axis at a distance x from the center of the ring is

$E = \dfrac{xQ}{4\pi\varepsilon_0(R^2+x^2)^{3/2}} = \dfrac{KxQ}{(R^2+x^2)^{3/2}}$

Differentiating with respect to x

$\dfrac{dE}{dx} = \dfrac{KQ(R^2+x^2)^{3/2} - KxQ(3/2)(R^2+x^2)^{11/2}2x}{(r^2+x^2)^3}$

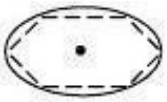

Since at a distance x, Electric field is maximum.

$\dfrac{dE}{dx} = 0 \Rightarrow KQ\,(R^2+x^2)^{3/2} - Kx^2\,Q3(R^2+x^2)^{1/2} = 0$

$\Rightarrow KQ\,(R^2+x^2)^{3/2} = Kx^2\,Q3(R^2+x^2)^{1/2} \Rightarrow R^2 + x^2 = 3x^2$

$\Rightarrow 2x^2 = R^2 \Rightarrow x^2 = \dfrac{R^2}{2} \Rightarrow x = \dfrac{R}{\sqrt{2}}$

43. Since it is a regular hexagon. So, it forms an equipotential surface. Hence the charge at each point is equal. Hence the net entire field at the centre is Zero.

44. Charge/Unit length $= \dfrac{Q}{2\pi a} = \lambda$; Charge of $d\ell = \dfrac{Qd\ell}{2\pi a}C$

Initially the electric field was '0' at the centre. Since the element '$d\ell$' is removed so, net electric field must

$\dfrac{K\times q}{a^2}$ Where q = charge of element $d\ell$

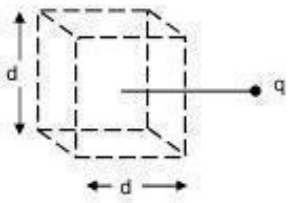

$E = \dfrac{Kq}{a^2} = \dfrac{1}{4\pi\varepsilon_0}\times\dfrac{Qd\ell}{2\pi a}\times\dfrac{1}{a^2} = \dfrac{Qd\ell}{8\pi^2\varepsilon_0 a^3}$

45. We know,

Electric field at a point due to a given charge

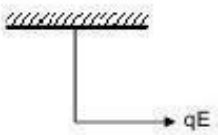

'E' $= \dfrac{Kq}{r^2}$ Where q = charge, r = Distance between the point and the charge

So, 'E' $= \dfrac{1}{4\pi\varepsilon_0}\times\dfrac{q}{d^2}$ [$\therefore$ r = 'd' here]

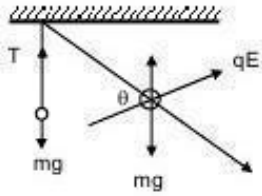

46. $E = 20\ kv/m = 20\times10^3\ v/m$, $m = 80\times10^{-5}\ kg$, $c = 20\times10^{-5}\ C$

$\tan\theta = \left(\dfrac{qE}{mg}\right)^{-1}$ [T Sin θ = mg, T Cos θ = qe]

$\tan\theta = \left(\dfrac{2\times10^{-8}\times20\times10^3}{80\times10^{-6}\times10}\right)^{-1} = \left(\dfrac{1}{2}\right)^{-1}$

$1 + \tan^2\theta = \dfrac{1}{4} + 1 = \dfrac{5}{4}$ [$\text{Cos}\,\theta = \dfrac{1}{\sqrt{5}}$, $\text{Sin}\,\theta = \dfrac{2}{\sqrt{5}}$]

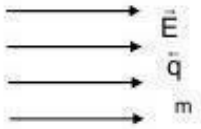

T Sin θ = mg $\Rightarrow T\times\dfrac{2}{\sqrt{5}} = 80\times10^{-6}\times10$

$\Rightarrow T = \dfrac{8\times10^{-4}\times\sqrt{5}}{2} = 4\times\sqrt{5}\times10^{-4} = 8.9\times10^{-4}$

47. Given

u = Velocity of projection, $\vec{E}$ = Electric field intensity

q = Charge; m = mass of particle

We know, Force experienced by a particle with charge 'q' in an electric field $\vec{E} = qE$

$\therefore$ acceleration produced = $\frac{qE}{m}$

As the particle is projected against the electric field, hence deceleration = $\frac{qE}{m}$

So, let the distance covered be 's'

Then, $v^2 = u^2 + 2as$ [where a = acceleration, v = final velocity]

Here $0 = u^2 - 2\times\frac{qE}{m}\times S \Rightarrow S = \frac{u^2m}{2qE}$ units

48. $m = 1\ g = 10^{-3}$ kg, $u = 0$, $q = 2.5 \times 10^{-4}$ C ; $E = 1.2 \times 10^4$ N/c ; $S = 40$ cm $= 4 \times 10^{-1}$ m

a) $F = qE = 2.5 \times 10^{-4} \times 1.2 \times 10^4 = 3$ N

So, $a = \frac{F}{m} = \frac{3}{10^{-3}} = 3 \times 10^3$

$E_q = mg = 10^{-3} \times 9.8 = 9.8 \times 10^{-3}$ N

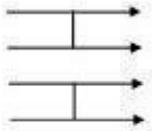

b) $S = \frac{1}{2}at^2$ or $t = \sqrt{\frac{2a}{g}} = \sqrt{\frac{2\times4\times10^{-1}}{3\times10^3}} = 1.63 \times 10^{-2}$ sec

$v^2 = u^2 + 2as = 0 + 2 \times 3 \times 10^3 \times 4 \times 10^{-1} = 24 \times 10^2 \Rightarrow v = \sqrt{24\times10^2} = 4.9 \times 10 = 49$ m/sec

work done by the electric force $w = F \rightarrow td = 3 \times 4 \times 10^{-1} = 12 \times 10^{-1} = 1.2$ J

49. $m = 100$ g, $q = 4.9 \times 10^{-5}$, $F_g = mg$, $F_e = qE$

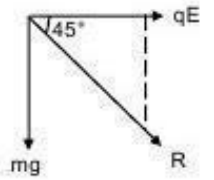

$\vec{E} = 2 \times 10^4$ N/C

So, the particle moves due to the et resultant R

$R = \sqrt{F_g^{\,2} + F_e^{\,2}} = \sqrt{(0.1\times9.8)^2 + (4.9\times10^{-5}\times2\times10^4)^2}$

$= \sqrt{0.9604 + 96.04\times10^{-2}} = \sqrt{1.9208} = 1.3859$ N

$\tan\theta = \frac{F_g}{F_e} = \frac{mg}{qE} = 1$ So, $\theta = 45°$

$\therefore$ Hence path is straight along resultant force at an angle 45° with horizontal

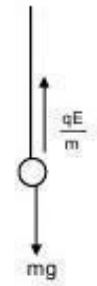

Disp. Vertical = (1/2) × 9.8 × 2 × 2 = 19.6 m

Disp. Horizontal = S = (1/2) $at^2 = \frac{1}{2}\times\frac{qE}{m}\times t^2 = \frac{1}{2}\times\frac{0.98}{0.1}\times2\times2 = 19.6$ m

Net Dispt. = $\sqrt{(19.6)^2 + (19.6)^2} = \sqrt{768.32} = 27.7$ m

50. $m = 40$ g, $q = 4 \times 10^{-6}$ C

Time for 20 oscillations = 45 sec. Time for 1 oscillation = $\frac{45}{20}$ sec

When no electric field is applied, $T = 2\pi\sqrt{\frac{\ell}{g}} \Rightarrow \frac{45}{20} = 2\pi\sqrt{\frac{\ell}{10}}$

$\Rightarrow \frac{\ell}{10} = \left(\frac{45}{20}\right)^2 \times \frac{1}{4\pi^2} \Rightarrow \ell = \frac{(45)^2\times10}{(20)^2\times4\pi^2} = 1.2836$

When electric field is not applied,

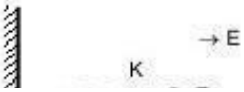

$T = 2\pi\sqrt{\frac{\ell}{g-a}}$ [$a = \frac{qE}{m} = 2.5$] $= 2\pi\sqrt{\frac{1.2836}{10-2.5}} = 2.598$

Time for 1 oscillation = 2.598

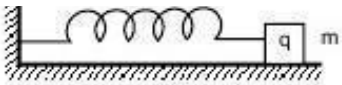

Time for 20 oscillation = 2.598 × 20 = 51.96 sec ≈ 52 sec.

51. $F = qE$, $F = -Kx$

Where x = amplitude

$qE = -Kx$ or $x = \frac{-qE}{K}$

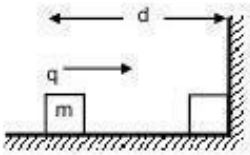

52. The block does not undergo. SHM since here the acceleration is not proportional to displacement and not always opposite to displacement. When the block is going towards the wall the acceleration is along displacement and when going away from it the displacement is opposite to acceleration.

Time taken to go towards the wall is the time taken to goes away from it till velocity is

$d = ut + (1/2)\,at^2$

$\Rightarrow d = \frac{1}{2} \times \frac{qE}{m} \times t^2$

$\Rightarrow t^2 = \frac{2dm}{qE} \Rightarrow t = \sqrt{\frac{2md}{qE}}$

$\therefore$ Total time taken for to reach the wall and com back (Time period)

$= 2t = 2\sqrt{\frac{2md}{qE}} = \sqrt{\frac{8md}{qE}}$

53. E = 10 n/c, S = 50 cm = 0.1 m

$E = \frac{dV}{dr}$ or, $V = E \times r = 10 \times 0.5 = 5$ cm

54. Now, $V_B - V_A$ = Potential diff = ? Charge = 0.01 C

Work done = 12 J Now, Work done = Pot. Diff × Charge

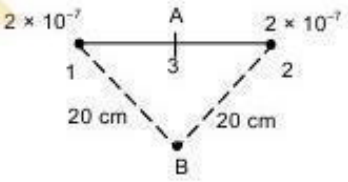

$\Rightarrow$ Pot. Diff $= \frac{12}{0.01} = 1200$ Volt

55. When the charge is placed at A,

$E_1 = \frac{Kq_1q_2}{r} + \frac{Kq_3q_4}{r}$

$= \frac{9\times10^9(2\times10^{-7})^2}{0.1} + \frac{9\times10^9(2\times10^{-7})^2}{0.1}$

$= \frac{2\times9\times10^9\times4\times10^{-14}}{0.1} = 72 \times 10^{-4}$ J

When charge is placed at B,

$E_2 = \frac{Kq_1q_2}{r} + \frac{Kq_3q_4}{r} = \frac{2\times9\times10^9\times4\times10^{-14}}{0.2} = 36 \times 10^{-4}$ J

Work done = $E_1 - E_2 = (72 - 36) \times 10^{-4} = 36 \times 10^{-4}$ J $= 3.6 \times 10^{-3}$ J

56. (a) A = (0, 0) B = (4, 2)

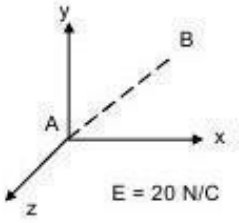

$V_B - V_A = E \times d = 20 \times \sqrt{16} = 80$ V

(b) A(4m, 2m), B = (6m, 5m)

$\Rightarrow V_B - V_A = E \times d = 20 \times \sqrt{(6-4)^2} = 20 \times 2 = 40$ V

(c) A(0, 0) B = (6m, 5m)

$\Rightarrow V_B - V_A = E \times d = 20 \times \sqrt{(6-0)^2} = 20 \times 6 = 120$ V.

57. (a) The Electric field is along x-direction

Thus potential difference between (0, 0) and (4, 2) is,

$\delta V = -E \times \delta x = -20 \times (40) = -80$ V

Potential energy $(U_B - U_A)$ between the points $= \delta V \times q$

$= -80 \times (-2) \times 10^{-4} = 160 \times 10^{-4} = 0.016$ J.

(b) A = (4m, 2m) B = (6m, 5m)

$\delta V = -E \times \delta x = -20 \times 2 = -40$ V

Potential energy $(U_B - U_A)$ between the points $= \delta V \times q$

$= -40 \times (-2 \times 10^{-4}) = 80 \times 10^{-4} = 0.008$ J

(c) A = (0, 0) B = (6m, 5m)

$\delta V = -E \times \delta x = -20 \times 6 = -120$ V

Potential energy $(U_B - U_A)$ between the points A and B

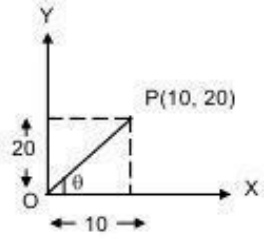

$= \delta V \times q = -120 \times (-2 \times 10^{-4}) = 240 \times 10^{-4} = 0.024$ J

58. $E = \left(\hat{i}20 + \hat{j}30\right)$ N/CV = at (2m, 2m) r = (2i + 2j)

So, $V = -\vec{E} \times \vec{r} = -(i20 + 30J)\,(2\,\hat{i} + 2i) = -(2 \times 20 + 2 \times 30) = -100$ V

59. $E = \vec{i} \times Ax = 100\ \vec{i}$

$$\int_v^0 dv = -\int E \times d\ell \qquad V = -\int_0^{10} 10x \times dx = -\int_0^{10} \frac{1}{2} \times 10 \times x^2$$

$$0 - V = -\left[\frac{1}{2} \times 1000\right] = -500 \Rightarrow V = 500 \text{ Volts}$$

60. $V(x, y, z) = A(xy + yz + zx)$

(a) $A = \dfrac{\text{Volt}}{m^2} = \dfrac{ML^2T^{-2}}{ITL^2} = [MT^{-3}I^{-1}]$

(b) $E = -\dfrac{\delta V\hat{i}}{\delta x} - \dfrac{\delta V\hat{j}}{\delta y} - \dfrac{\delta V\hat{k}}{\delta z} = -\left[\dfrac{\delta}{\delta x}[A(xy+yz+zx) + \dfrac{\delta}{\delta y}[A(xy+yz+zx) + \dfrac{\delta}{\delta z}[A(xy+yz+zx)\right]$

$= -\left[(Ay + Az)\hat{i} + (Ax + Az)\hat{j} + (Ay + Ax)\hat{k}\right] = -A(y+z)\hat{i} + A(x+z)\hat{j} + A(y+x)\hat{k}$

(c) A = 10 SI unit, r = (1m, 1m, 1m)

$E = -10(2)\,\hat{i} - 10(2)\,\hat{j} - 10(2)\,\hat{k} = -20\,\hat{i} - 20\,\hat{j} - 20\,\hat{k} = \sqrt{2o^2 + 20^2 + 20^2} = \sqrt{1200} = 34.64 \approx 35$ N/C

61. $q_1 = q_2 = 2 \times 10^{-5}$ C

Each are brought from infinity to 10 cm a part $d = 10 \times 10^{-2}$ m

So work done = negative of work done. (Potential E)

$$P.E = \int_{\infty}^{10} F \times ds \qquad P.E. = K \times \frac{q_1 q_2}{r} = \frac{9 \times 10^9 \times 4 \times 10^{-10}}{10 \times 10^{-2}} = 36 \text{ J}$$

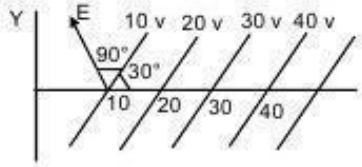

62. (a) The angle between potential E $d\ell$ = dv

Change in potential = 10 V = dV

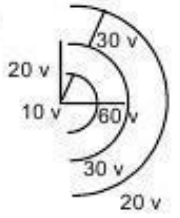

As E = ⊥r dV (As potential surface)

So, E $d\ell$ = dV ⇒ E $d\ell$ Cos(90° + 30°) = – dv

⇒ E(10× 10^{-2}) cos 120° = – dV

$$\Rightarrow E = \frac{-dV}{10 \times 10^{-2} \text{Cos}120^\circ} = -\frac{10}{10^{-1} \times (-1/2)} = 200 \text{ V/m making an angle } 120^\circ \text{ with y-axis}$$

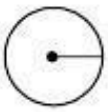

(b) As Electric field intensity is ⊥r to Potential surface

$$\text{So, } E = \frac{kq}{r^2} r = \frac{kq}{r} \Rightarrow \frac{kq}{r} = 60 \text{ v} \qquad q = \frac{6}{K}$$

$$\text{So, } E = \frac{kq}{r^2} = \frac{6 \times k}{k \times r^2} \text{ v.m} = \frac{6}{r^2} \text{ v.m}$$

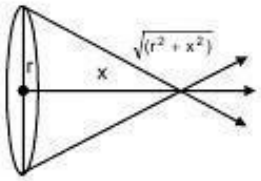

63. Radius = r So, 2πr = Circumference

Charge density = λ Total charge = 2πr × λ

$$\text{Electric potential} = \frac{Kq}{r} = \frac{1}{4\pi\varepsilon_0} \times \frac{2\pi r\lambda}{(x^2 + r^2)^{1/2}} = \frac{r\lambda}{2\varepsilon_0 (x^2 + r^2)^{1/2}}$$

$$\text{So, Electric field} = \frac{V}{r}\text{Cos}\theta$$

$$= \frac{r\lambda}{2\varepsilon_0 (x^2 + r^2)^{1/2}} \times \frac{1}{(x^2 + r^2)^{1/2}}$$

$$= \frac{r\lambda}{2\varepsilon_0 (x^2 + r^2)^{1/2}} \times \frac{x}{(x^2 + r^2)^{1/2}} = \frac{r\lambda x}{2\varepsilon_0 (x^2 + r^2)^{3/2}}$$

64. $\vec{E}$ = 1000 N/C

(a) $V = E \times d\ell = 1000 \times \dfrac{2}{100} = 20$ V

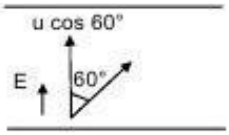

(b) u = ? $\vec{E}$ = 1000, = 2/100 m

$$a = \frac{F}{m} = \frac{q \times E}{m} = \frac{1.6 \times 10^{-19} \times 1000}{9.1 \times 10^{-31}} = 1.75 \times 10^{14} \text{ m/s}^2$$

$0 = u^2 - 2 \times 1.75 \times 10^{14} \times 0.02 \Rightarrow u^2 = 0.04 \times 1.75 \times 10^{14} \Rightarrow u = 2.64 \times 10^6$ m/s.

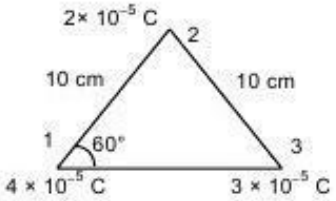

(c) Now, U = u Cos 60° V = 0, s = ?
$a = 1.75 \times 10^{14}$ m/s² $V^2 = u^2 - 2as$

$$\Rightarrow s = \frac{(u\cos 60°)^2}{2\times a} = \frac{\left(2.64\times 10^6 \times \frac{1}{2}\right)^2}{2\times 1.75\times 10^{14}} = \frac{1.75\times 10^{12}}{3.5\times 10^{14}} = 0.497 \times 10^{-2} \approx 0.005 \text{ m} \approx 0.50 \text{ cm}$$

65. E = 2 N/C in x-direction
(a) Potential aat the origin is O. $dV = -E_x\,dx - E_y\,dy - E_z\,dz$
$\Rightarrow V - 0 = -2x \Rightarrow V = -2x$
(b) $(25 - 0) = -2x \Rightarrow x = -12.5$ m
(c) If potential at origin is 100 v, $v - 100 = -2x \Rightarrow V = -2x + 100 = 100 - 2x$
(d) Potential at ∞ IS 0, $V - V' = -2x \Rightarrow V' = V + 2x = 0 + 2\infty \Rightarrow V' = \infty$
Potential at origin is ∞. No, it is not practical to take potential at ∞ to be zero.

66. Amount of work done is assembling the charges is equal to the net potential energy
So, P.E. = $U_{12} + U_{13} + U_{23}$

$$= \frac{Kq_1q_2}{r_{12}} + \frac{Kq_1q_3}{r_{13}} + \frac{Kq_2q_3}{r_{23}} = \frac{K\times 10^{-10}}{r}[4\times 2 + 4\times 3 + 3\times 2]$$

$$= \frac{9\times 10^9 \times 10^{-10}}{10^{-1}}(8 + 12 + 6) = 9 \times 26 = 234 \text{ J}$$

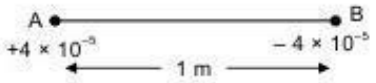

67. K.C. decreases by 10 J. Potential = 100 v to 200 v.
So, change in K.E = amount of work done
$\Rightarrow 10J = (200 - 100)\text{ v} \times q_0 \Rightarrow 100\, q_0 = 10$ v
$\Rightarrow q_0 = \frac{10}{100} = 0.1$ C

68. m = 10 g; $F = \frac{KQ}{r} = \frac{9\times 10^9 \times 2\times 10^{-4}}{10\times 10^{-2}}$ $F = 1.8 \times 10^{-7}$

$F = m \times a \Rightarrow a = \frac{1.8\times 10^{-7}}{10\times 10^{-3}} = 1.8 \times 10^{-3}$ m/s²
$V^2 - u^2 = 2as \Rightarrow V^2 = u^2 + 2as$
$V = \sqrt{0 + 2\times 1.8\times 10^{-3}\times 10\times 10^{-2}} = \sqrt{3.6\times 10^{-4}} = 0.6 \times 10^{-2} = 6 \times 10^{-3}$ m/s.

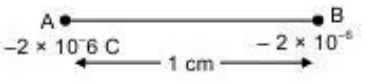

69. $q_1 = q_2 = 4 \times 10^{-5}$; s = 1m, m = 5 g = 0.005 kg
$F = K\frac{q^2}{r^2} = \frac{9\times 10^9 \times (4\times 10^{-5})^2}{1^2} = 14.4$ N

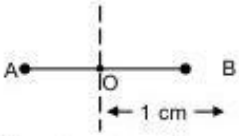

Acceleration 'a' = $\frac{F}{m} = \frac{14.4}{0.005} = 2880$ m/s²
Now u = 0, s = 50 cm = 0.5 m, a = 2880 m/s², V =?
$V^2 = u^2 + 2as \Rightarrow V^2 = = 2 \times 2880 \times 0.5$
$\Rightarrow V = \sqrt{2880} = 53.66$ m/s ≈ 54 m/s for each particle

70. E = 2.5 × 104 P = 3.4×10^{-30} $\tau = PE \sin\theta$
$= P \times E \times 1 = 3.4 \times 10^{-30} \times 2.5 \times 10^4 = 8.5 \times 10^{-26}$

71. (a) Dipolemoment = $q \times \ell$
(Where q = magnitude of charge ℓ = Separation between the charges)
$= 2 \times 10^{-6} \times 10^{-2}$ cm $= 2 \times 10^{-8}$ cm

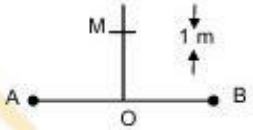

(b) We know, Electric field at an axial point of the dipole

$= \frac{2KP}{r^3} = \frac{2\times 9\times 10^9 2\times 10^{-8}}{(1\times 10^{-2})^3} = 36 \times 10^7$ N/C

(c) We know, Electric field at a point on the perpendicular bisector about 1m away from centre of dipole.

$= \frac{KP}{r^3} = \frac{9\times 10^9 2\times 10^{-8}}{1^3} = 180$ N/C

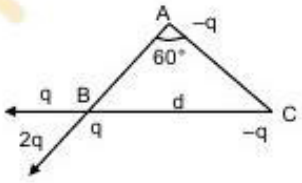

72. Let –q & –q are placed at A & C

Where 2q on B So length of A = d

So the dipole moment = (q × d) = P

So, Resultant dipole moment

$P = [(qd)^2 + (qd)^2 + 2qd \times qd \cos 60°]^{1/2} = [3\, q^2 d^2]^{1/2} = \sqrt{3}\, qd = \sqrt{3}\, P$

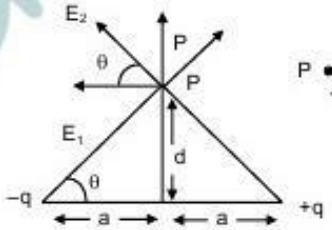

73. (a) P = 2qa

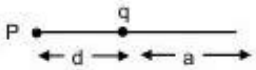

(b) $E_1 \sin\theta = E_2 \sin\theta$ Electric field intensity

$= E_1 \cos\theta + E_2 \cos\theta = 2 E_1 \cos\theta$

$E_1 = \dfrac{Kqp}{a^2 + d^2}$ so $E = \dfrac{2KPQ}{a^2 + d^2} \dfrac{a}{(a^2 + d^2)^{1/2}} = \dfrac{2Kq \times a}{(a^2 + d^2)^{3/2}}$

When a << d $= \dfrac{2Kqa}{(d^2)^{3/2}} = \dfrac{PK}{d^3} = \dfrac{1}{4\pi\varepsilon_0} \dfrac{P}{d^3}$

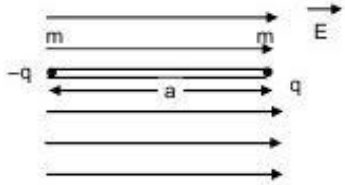

74. Consider the rod to be a simple pendulum.

For simple pendulum $T = 2\pi\sqrt{\ell / g}$ (ℓ = length, q = acceleration)

Now, force experienced by the charges

F = Eq Now, acceleration = $\dfrac{F}{m} = \dfrac{Eq}{m}$

Hence length = a so, Time period = $2\pi\sqrt{\dfrac{a}{(Eq/m)}} = 2\pi\sqrt{\dfrac{ma}{Eq}}$

75. 64 grams of copper have 1 mole 6.4 grams of copper have 0.1 mole

1 mole = No atoms 0.1 mole = (no × 0.1) atoms

$= 6 \times 10^{23} \times 0.1$ atoms $= 6 \times 10^{22}$ atoms

1 atom contributes 1 electron 6×10^{22} atoms contributes 6×10^{22} electrons.
